Outline
1. Working with dates in SAS
2. Introduction to arrays
3. Checking the uniqueness of ID numbers
4. Verifying the check digit on PNRs
5. Customised notes and warnings in the log
6. Counting the number of deleted observations by writing them to a SAS data set

Working with dates in SAS
• From its inception, the SAS System has stored date values as an offset in days from January 1, 1960.
• Leap years, century, and fourth-century adjustments are made automatically. Leap seconds are ignored, and the SAS System does not adjust for daylight saving time.
• This method of date representation means that calculations and comparisons of SAS date values will produce correct results, regardless of century.
• SAS users can convert external data to or from SAS date values by the use of various informats, formats, and functions.

Reading raw data into SAS date variables
• Raw data can be read into SAS date variables using an appropriate informat.
  data temp;
  input date yymmdd8.;
  cards;
  19310317
  19681224
  19651128
  19990914
  run;
  proc print; ==> Obs DATE
  var date;
  format date date.;
  run;
  1 17MAR31
  2 24DEC68
  3 28NOV65
  4 14SEP99

Converting character or numeric variables to SAS date variables
• This can be done using the INPUT function. The following line of code extracts date of birth from PNR and writes it out as a SAS date variable.
  birth=input(substr(pnr,2,6),yymmdd.);
• If the values of year, month, and day are stored in separate variables, these can be written to a single SAS date variable using the MDY function:
  datevar=mdy(month, day, year);

Before matching your data with registry data
• We often match our cohorts with registry data to obtain information on exposures and/or outcomes.
• Before performing such matching it is advisable to verify that all identification numbers (personnummer) are valid.
• An individual with an invalid personnummer cannot, for example, be identified as having a diagnosis of cancer.
• Should perform the following checks:
  1. Check that all personal identity numbers are unique.
  2. Check that the ‘birth number’ is appropriate for the sex of the patient (e.g. in a cohort of prostate cancer patients all birth numbers should be odd).
  3. Verify the check digit on each personnummer.

Checking the uniqueness of ID numbers
• Raw data can be read into SAS date variables using an appropriate informat.
  data temp;
  input id start end sex;
  informat start end ddmmyy8.;
  format start end date8.;
  cards;
  1 281165 070599 1
  2 230489 120193 2
  3 011295 . .
  3 011295 181089 2
  4 020773 010399 1
  run;
  proc print; ==> Obs DATE
  var date;
  format date date.;
  run;
  1 17MAR31
  2 24DEC68
  3 28NOV65
  4 14SEP99

Informat and format commands can be used to extract the calendar year from the personnummer:
• Personnummer includes the calendar year in the first three digits.
• Before matching with registry data, ensure that all personnummer values are valid for the year in which the patient was born.

Example:
  informat start end ddmmyy8.;
  format start end date8.;
  cards;
  1 281165 070599 1
  2 230489 120193 2
  3 011295 . .
  3 011295 181089 2
  4 020773 010399 1
  run;
Can use the nodupkey option on PROC SORT

175 proc sort data=temp out=sorted nodupkey;
176 by id;
177 run;

NOTE: 1 observations with duplicate key values were deleted.
NOTE: There were 5 observations read from the data set WORK.TEMP.
NOTE: The data set WORK.SORTED has 4 observations and 4 variables.

• But we have no control over which observation is deleted!

<table>
<thead>
<tr>
<th>Obs</th>
<th>ID</th>
<th>START</th>
<th>END</th>
<th>SEX</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>28Nov65</td>
<td>07May99</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>23Apr89</td>
<td>12Jan93</td>
<td>2</td>

<tr>
<td>3</td>
<td>3</td>
<td>01Dec95</td>
<td></td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td>02Jul73</td>
<td>01Mar99</td>
<td>1</td>
</tr>
</tbody>
</table>

Preferable to write the duplicate observations to a data file so we can study them

181 data unique dups;
182 set temp;
183 by id;
184 if first.id and last.id then output unique;
185 else output dups;
186 run;

NOTE: There were 5 observations read from the data set WORK.TEMP.
NOTE: The data set WORK.UNIQUE has 3 observations and 4 variables.
NOTE: The data set WORK.DUPS has 2 observations and 4 variables.

• Anna Torr˚ang described the first. and last. variables and the output statement.

• If an ID number if unique then it must be both the first and the last observation in the data set with the ID number.

Verifying the check digit on PNRs

• Swedish personal identification numbers (PNRs) comprise 10 digits (12 if century of birth is included).

• The first 6 digits represent date of birth (YYMMDD), followed by a 3-digit birth number (födelsenummer), which is even for females and odd for males, and the tenth digit is a check digit which can be constructed from the preceding nine digits.

• Further details of the personnummer along with the algorithm for verifying the check digit can be found at Riksskatteverkets site. http://www.rsv.se/pdf/70407.pdf

Algorithm for calculating the check digit

• First multiply each of the first nine digits in the PNR by the digits 2,1,2,1,2,1,2,1,2 and calculate the cumulative sum of each of these 9 calculations.

• If the product results in a number greater than 10, then add the individual digits.

• For example, \(9 \times 2 = 18\), so we add 9 (the sum of 1 and 8) to the cumulative sum in the example below.

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>1</td>
<td>0</td>
<td>3</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>0</td>
<td>3</td>
</tr>
<tr>
<td>2</td>
<td>7</td>
<td>0</td>
<td>9</td>
</tr>
</tbody>
</table>

• In the example above, the cumulative sum is 37. The check digit is the number we would have to add to the product sum in order to obtain a multiple of 10.

In the above example, we would need to add 3, so the check digit is 3.

• If the cumulative sum is a multiple of 10 then the check digit is 0.

Algorithm for calculating the check digit

• First multiply each of the first nine digits in the PNR by the digits 2,1,2,1,2,1,2,1,2 and calculate the cumulative sum of each of these 9 calculations.

• If the product results in a number greater than 10, then add the individual digits.

• For example, \(9 \times 2 = 18\), so we add 9 (the sum of 1 and 8) to the cumulative sum in the example below.

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>1</td>
<td>0</td>
<td>3</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>0</td>
<td>3</td>
</tr>
<tr>
<td>2</td>
<td>7</td>
<td>0</td>
<td>9</td>
</tr>
</tbody>
</table>

• In the example above, the cumulative sum is 37. The check digit is the number we would have to add to the product sum in order to obtain a multiple of 10.

In the above example, we would need to add 3, so the check digit is 3.

• If the cumulative sum is a multiple of 10 then the check digit is 0.

Introduction to arrays

• A SAS array is nothing more than a collection of variables (of the same type), in which each variable can be identified by referring to the array and, by means of an index, to the location of the variable within the array.

• SAS arrays are defined using the ARRAY statement, and are only valid within the data step in which they are defined.

• The syntax for the array statement is:

  ARRAY array-name (subscript) <#> < length >
<< array-elements > <( initial-values )>>

• array-name must follow the naming rules for SAS variables.

• { subscript } is the dimension (possibly multiple) of the array, and can be omitted or specified as * in which case SAS infers the dimension from the number of array elements.

• < array-elements > is the list of array elements (variables) which can be omitted if the dimension is given, in which case SAS creates variables called array-name1 to array-name(n) where {n} is the dimension of the array.

• For example:

  array wt {50};
  do i=1 to 50;
  if weight(i)=-999 then weight(i)=.;
  end;

• The variables do not have to be named wt1, wt2, wt3, ... wt50.

  array vars pnr height weight bmi sex;
  array vars pnr--sex;
  array vars _numeric_;
Example using data from the Swedish Birth Register

- For each record, we have information on up to 12 'events'. The event type (usually a birth) is stored in the variables type1-type12 and the corresponding date is stored in the variables date1-date12.
- The coding for the 'type' variables is:
  0 = stillbirth
  1 = live boy
  2 = live girl
  6 = immigration
- For each woman, we want to count the total number of live births, the total number of completed pregnancies (live births plus still births), and extract the emigration date for the women who emigrated.

```sas
array type type1-type12;
array date date1-date12;
births=0; comppreg=0; emigrate=0;
doi=1 to 12;
if type[i] in (1,2) then births=sum(births,1);
if type[i] in (0,1,2) then comppreg=sum(comppreg,1);
if type[i] in (6) then do;
  emigrate=1;
  emi_date=input(date[i],ymmd.);
end;
end;
label births='No. live births'
comppreg='No. completed pregnancies'
emigrate='Emigration indicator'
emi_date='Date of emigration (SAS date)';
```

SAS code for calculating the check digit

- Available at http://www.pauldickman.com/teaching/sas/pnr_check.html

```sas
/* generate some test data */
data temp;
input pnr $ 1-10 sex 12;
cards;
3103170993 1
3103170999 1
6812241450 1
6812241457 1
7511281896 2
7805062242 2 ;
run;
```

```sas
/** extract the check digit from PNR **/
chk=substr(pnr,10,1);
/** calculate the correct check digit **/
corr_chk=mod(10-mod(sum,10),10);
if chk=corr_chk then result='ok';
else result='bad';
label chk='Actual check number'
corr_chk='Correct check number'
pnr='Personnummer (10 digits)'
run;
```

Output from PROC PRINT

```sas
Obs PNR CHK PRODUCT SUM CORR_CHK RESULT
1 3103170993 3 6103270918 37 3 ok
2 3103170999 9 6103270918 37 3 bad
3 6812241450 0 12822442810 30 0 ok
4 6812241457 7 12822442810 30 0 bad
5 7511281896 6 14521482818 44 6 ok
6 7805062242 5 1480506428 38 2 bad
```

How you could use this code in practice

- Instead of
  ```sas
  if chk=corr_chk then result='ok';
  else result='bad';
  ```
  You might use
  ```sas
  data all pnr_bad;
  set mydata;
  if chk=corr_chk then output pnr_bad;
  output all;
  run;
  ```
- Or you might just use the original code and then use
  ```sas
  proc print data=pnr_chk(where=(result='bad'));
  var pnr chk product sum corr_chk result;
  run;
  ```
Verifying that gender agrees with that implied by the PNR

- Assume we have a variable called SEX which takes the values 1 for males and 2 for females.

```sas
/* 11th digit of PNR odd => male (sex=1), else female (sex=2) */
if mod(input(substr(pnr,11,1),1.),2)=1 then sex_chk=1;
else sex_chk=2;
if sex ne sex_chk then output badsex;
```

Customised notes and warnings in the log

- If you 'put' a text string to the log which begins with 'ERROR:', 'WARNING:', or 'NOTE:', then SAS will format the text as an ERROR, WARNING, or NOTE respectively.
- That is the text will appear in the log file using the designated colour (red, green, and blue by default).
- This provides an efficient way of performing and documenting data checking/cleaning.

```sas
data temp;
  input id start end sex;
  informat start end ddmmyy8.;
  format start end date8.;
  cards;
  1 281165 070599 1
  2 230489 120193 2
  3 011295 181089 2
  4 020773 010399 1
  run;
data new;
  set temp;
  if start gt end then
  put 'ERROR: end before start: ' id= start= end= ;
  run;
```

Extract from the log file

```sas
235 data new;
236 set temp;
237 if start gt end then
238 put 'ERROR: end before start: ' id= start= end= ;
239 run;
```

```sas
ERROR: end before start: ID=3 START=01DEC95 END=18OCT89
NOTE: There were 4 observations read from the data set WORK.TEMP.
NOTE: The data set WORK.NEW has 4 observations and 4 variables.
```

```sas
27
```

Another example

```sas
if sex=1 then hi_bmi=(bmi>29);
else if sex=2 then hi_bmi=(bmi>28);
else put 'WARNING: Invalid value for sex: ' pnr= sex= ;
```

- This is a simple way of putting logic checks in your program.

Counting the number of deleted observations by writing them to a SAS data set

```sas
data analysis noninv prevcan premeno no_age;
  set emma.main;
  /* non-invasive */
  if 11<=histop<=19 then do; output noninv; delete; end;
  /* previous cancer */
  if 1<=prevcanc<=2 then do; output prevcan; delete; end;
  /* premenopausal */
  if mptype=0 then do; output premeno; delete; end;
  /* age at first birth unknown */
  if agefb=. and parity>0 then do; output no_age; delete; end;
  output analysis;
run;
```

```sas
29
```

Extract from the log file

```sas
286 data analysis noninv prevcan premeno no_age no_ht;
287 set emma.main;
288 /* non-invasive */
289 if li<=histop<=19 or histop>22 then do; output noninv; delete; end;
290 /* previous cancer */
291 if l<=prevcanc<=2 then do; output prevcan; delete; end;
292 /* premenopausal */
293 if nptype=0 then do; output premeno; delete; end;
294 /* age at first birth unknown */
295 if agefb=. and parity>0 then do; output no_age; delete; end;
296 output analysis; run;
```

```sas
NOTE: There were 7420 observations read from the data set EMMA.MAIN.
NOTE: The data set WORK.ANALYSIS has 6207 observations and 89 variables.
```

```sas
NOTE: The data set WORK.NONINV has 352 observations and 89 variables.
NOTE: The data set WORK.PREVCAN has 471 observations and 89 variables.
NOTE: The data set WORK.PREMENO has 350 observations and 89 variables.
NOTE: The data set WORK.NO_AGE has 6 observations and 89 variables.
NOTE: The data set WORK.NO_HT has 34 observations and 89 variables.
```

```sas
NOTE: DATA statement used:
  real time 2:22.59
  cpu time 0.53 seconds
```

```sas
29
```
